RESTful Diner

A Restaurant orders management APIs system

Conclusions

Introduction

The Problem

In a far away land, there is a restaurant that is serving every day thousands of hungry customers. The restaurant owner needs a system to keep track of all the orders that are coming in, and that can also help him to analyze the data in order to improve the service that he is offering to his customers.

The restaurant owner understands that the data that he is collecting is very valuable, and he wants to make it available to the public, so that other willing Data Scientists can help him to understand any hidden insight on the data, and to suggest him how to improve his business.

Introduction

Envisioned Solution

The solution of the problem is to design a system that can handle the restaurant orders data, and that can also provide an API to access the data in a simple and efficient way.

In a few words, an Open Data API system is exactly what the restaurant owner needs.

The whole code of the project is available on GitHub at https://github.com/ enstit/RESTfulDiner.

The first step of our development to identify the use cases of our system. We have identified four main use cases:

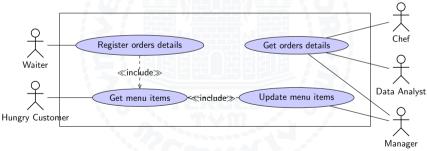

Figure: Use cases diagram

E/R Diagram

Next, the E/R diagram was designed to represent the data model of the system:

Figure: E/R diagram

Introduction

Data model (logical) implementation I

The data model has been implemented using the SQLAlchemy ORM, which provides a high-level interface to the (PostgreSQL, in this case) database.

```
class BaseModel (DeclarativeBase):
        __abstract__ = True
        Odeclared attr
        def id(cls) -> Mapped[UUIDType]:
             return mapped column (
                  cd ID
                  default=lambda: uuid8(domain=cls. name),
                  primary key=True.
                  comment=f"Unique {c|s.__name__} instance identifier",
sort order=-1, # Ensure the id is the first column in the table
10
11
12
```

Any class inherits from the BaseModel class and is automatically mapped to a table in the database.

Data model (logical) implementation II

```
1 class Department (BaseModel):
       name: Mapped[str] = mapped column(
            cd SHORT NAME
            unique=True
           comment="Unique name of the department"
       color: Mapped[Optional[str]] = mapped column(
8
            cd SHORT NAME.
           comment=(
10
                "A color between the Recognized color keyword names."
11
                "See also https://www.w3.org/TR/SVG11/types.html#ColorKeywords"
12
13
       printer id: Mapped[Optional[UUIDType]] = mapped column(
14
15
            cd \square \overline{D} .
16
            Foreign Key ("printer.id"),
17
            nullable=True.
            default=None,
18
           comment="|dentifier of the printer the department is equipped with",
19
20
```

Data model (physical) implementation

Since we are using an ORM, the physical implementation of the data model is automatically generated by the ORM itself. This is, for example, the code for the department table:

```
CREATE TABLE department (
    id UUID NOT NULL.
    name VARCHAR(63) NOT NULL.
    color VARCHAR(63),
    printer id UÙID,
    PRIMARY KEY (id)
    UNIQUE (name).
    FOREIGN KEY (printer id) REFERENCES printer (id)
10 COMMENT ON COLUMN department id | S 'Unique Department instance identifier';
11 COMMENT ON COLUMN department name IS 'Unique name of the department':
12 COMMENT ON COLUMN department color | S 'A color between the Recognized color keyword names. See
         also https://www.w3.org/TR/SVG11/types.html#ColorKeywords ;
13 COMMENT ON COLUMN department printer id IS Identifier of the printer the department is
       equipped with
```

The RESTful API has been implemented using the Flask web framework.

```
1 class DepartmentResource(ProtectedResource):
       def get (
           self , *, id: str | None = None, name: str | None = None
       ) -> tup e [ dict . int ] :
           if id or name:
               department = (
                   db session query (Department)
                    .where(Department id == id if id else Department name == name)
                    .one or none()
10
11
                if department:
                   return DepartmentDTO from model (department), 200
12
               return {"message": "Department was not found"} 404
13
14
           departments = db session query (Department) all ()
15
           return Department DTO from model list (departments), 200
```

API resources II

```
" @context " : {
       "schema": "https://schema.org/".
       "self": "@id".
       "type": "@type".
       "name": "schema:name",
       "printer": {
         "Qid": "schema: is Related To".
         "@tvpe": "@id"
10
11
       "license": {
12
         "Qid": "schema: license".
13
         "@tvpe": "@id"
14
15
     "license ": "https://creativecommons.org/licenses/by/4.0/",
16
     "data": {
17
18
       "self": "http://127.0.0.1:5000/api/v1/departments/5b11618c-51f5-8000-8000-6496d5c5c0cf",
19
       "type": "schema: Organization",
20
       "name": "Kitchen".
21
       "printer": "http://127.0.0.1:5000/api/v1/printers/5b11618c-51f5-8000-8000-2a5553677712"
22
23
```

System implementatio

Demo

A live demo of the system is available at https://diner.enricostefanel.it.

Figure: Demo of the system using Postman

Linked Open Data^[1] requirements I

Make your stuff available on the Web (whatever format) under an open license.

Make it available as structured data (e.g., Excel instead of image scan of a table).

Make it available in a non-proprietary open format (e.g., CSV instead of Excel).

These requirements are satisfied by our RESTful API that allows publicly access to data in JSON-LD^[2] format and provide them under Creative Commons license.

Linked Open Data^[1] requirements II

Use URIs to denote things, so that people can point at your stuff.

Link your data to other data to provide context.

Every resource in the system is identified by a URI, and can be accessed by a simple HTTP GET request to that URI. A relation between resources is established by linking them in the JSON response.

FAIR^[3] principles requirements |

• F1. (Meta)data are assigned a globally unique and persistent identifier

Open Data principles

- **F2**. Data are described with rich metadata (defined by R1 below)
- F3. Metadata clearly and explicitly include the identifier of the data they describe
- F4. (Meta)data are registered or indexed in a searchable resource

The JSON-LD data representation includes the URI of the resource itself and the related resources. Since the metadata is provided together with the data, there is no need to include the identifier of the data in the metadata.

FAIR^[3] principles requirements ||

- A1. (Meta)data are retrievable by their identifier using a standardized communications protocol
- A1.1 The protocol is open, free, and universally implementable
- A1.2 The protocol allows for an authentication and authorization procedure, where necessary

Open Data principles

• A2. Metadata are accessible, even when the data are no longer available

The HTTP protocol ensured that (meta)data is freely accessible, allowing for an authorization procedure where necessary (e.g. POST operations).

FAIR^[3] principles requirements III

Interoperable

- I1. (Meta)data use a formal, accessible, shared, and broadly applicable language for knowledge representation
- 12. (Meta)data use vocabularies that follow FAIR principles
- 13. (Meta)data include qualified references to other (meta)data

FAIR^[3] principles requirements IV

Reusable

- R1. Meta(data) are richly described with a plurality of accurate and relevant attributes
- R1.1 (Meta)data are released with a clear and accessible data usage license
- R1.2 (Meta)data are associated with detailed provenance
- R1.3 (Meta)data meet domain-relevant community standards

Data Management Plan I

- How will the data be created? The data will be created by the restaurant staff, who will use the system to manage the restaurant's departments, tables, and printers.
- 2 How will the data be documented? The data will be documented in the system's database, and the API will provide a JSON-LD representation of the data.

Open Data principles

- **3 Who will access the data?** The data will be publicly accessible through the RESTful API.
- 4 How will the data be stored? The data will be stored by the system's database, which is a PostgreSQL database. In case, the database can also be installed on a cloud service.

Data Management Plan II

6 How will the data be shared? The data will be shared through the RESTful API, which will provide a JSON-LD representation of the data for basic HTTP requests (GET, POST, PUT, DELETE).

Open Data principles

- **6** How will the data be preserved? The data will be preserved by the system's database, which will be backed up regularly to ensure data integrity.
- Who will back up the data? The data will be backed up by the system administrator, who will ensure that the database is backed up regularly.

The real world scenario

The system we presented today is not a requirements from a very far away land, after all...
